

Experimental Probability Vs. Theoretical Probability

Objectives & Standards

- To explore experimental and theoretical probability with experiments and simulations
- To calculate and compare both probabilities
- MA.E.2.3.1
- MA.E.3.3.1

What do you know about probability?

- Probability is a number from 0 to 1 that tells you how likely something is to happen.
- Probability can have two approaches
 - experimental probability
 - theoretical probability

Key Words

- Experimental probability
- Theoretical probability
- Law of Large Numbers
- Outcome
- Event
- Random

Experimental vs. Theoretical

Experimental probability:

$$P(\text{event}) = \frac{\text{number of times event occurs}}{\text{total number of trials}}$$

Theoretical probability:

$$P(E) = \frac{\text{number of favorable outcomes}}{\text{total number of possible outcomes}}$$

How can you tell which is experimental and which is theoretical probability?

Experimental:

You tossed a coin 10 times and recorded a head 3 times, a tail 7 times

$$P(\text{head}) = 3/10$$

$$P(\text{tail}) = 7/10$$

Theoretical:

Toss a coin and getting a head or a tail is $1/2$.

$$P(\text{head}) = 1/2$$

$$P(\text{tail}) = 1/2$$

Experimental probability

Experimental probability is found by repeating an **experiment** and observing the **outcomes**.

$$P(\text{head}) = 3/10$$

A head shows up 3 times out of 10 trials,

$$P(\text{tail}) = 7/10$$

A tail shows up 7 times out of 10 trials

Theoretical probability

$$P(\text{head}) = 1/2$$

$$P(\text{tail}) = 1/2$$

Since there are only two outcomes, you have 50/50 chance to get a head or a tail.

Compare experimental and theoretical probability

Both probabilities are ratios that compare the number of favorable outcomes to the total number of possible outcomes

$$P(\text{head}) = 3/10$$

$$P(\text{tail}) = 7/10$$

$$P(\text{head}) = 1/2$$

$$P(\text{tail}) = 1/2$$

Identifying the Type of Probability

- A bag contains three red marbles and three blue marbles.

$$P(\text{red}) = \frac{3}{6} = \frac{1}{2}$$

✓ Theoretical

(The result is based on the possible outcomes)

Identifying the Type of Probability

Trial	Red	Blue
1		1
2	1	
3		1
4	1	
5		1
6		1
Total	2	4
Exp. Prob	1/3	2/3

- You draw a marble out of the bag, record the color, and replace the marble. After 6 draws, you record 2 red marbles

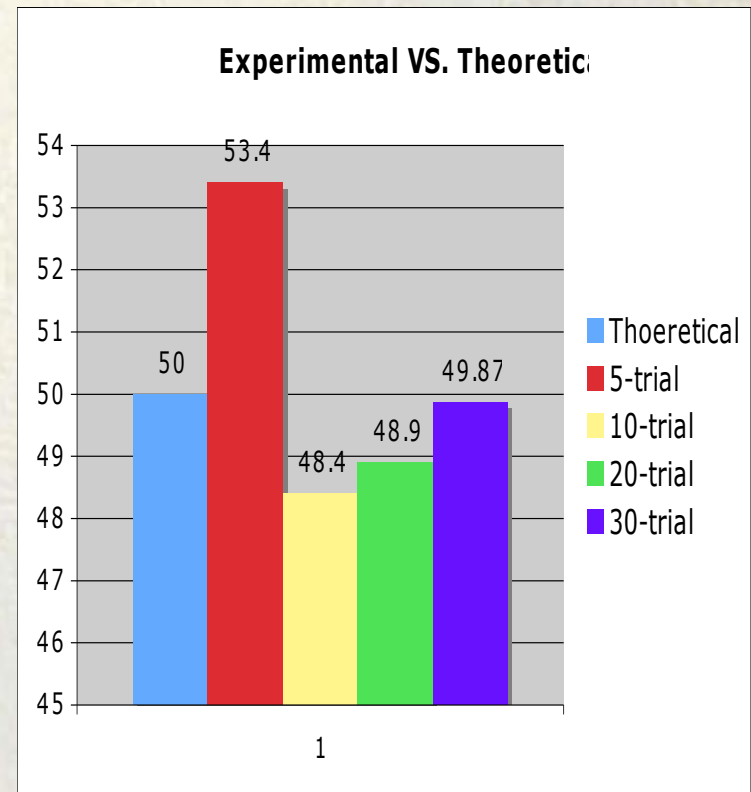

$$P(\text{red}) = \frac{2}{6} = \frac{1}{3}$$

✓ Experimental

(The result is found by repeating an experiment.)

How come I never get a theoretical value in both experiments? Tom asked.

- If you repeat the experiment many times, the results will get closer to the theoretical value.
- Law of the Large Numbers

Law of the Large Numbers 101

- The Law of Large Numbers was first published in 1713 by Jacob Bernoulli.
- It is a fundamental concept for probability and statistic.
- This Law states that as the number of trials increase, the experimental probability will get closer and closer to the theoretical probability.

Contrast experimental and theoretical probability

Experimental probability is the result of an experiment.

Theoretical probability is what is expected to happen.

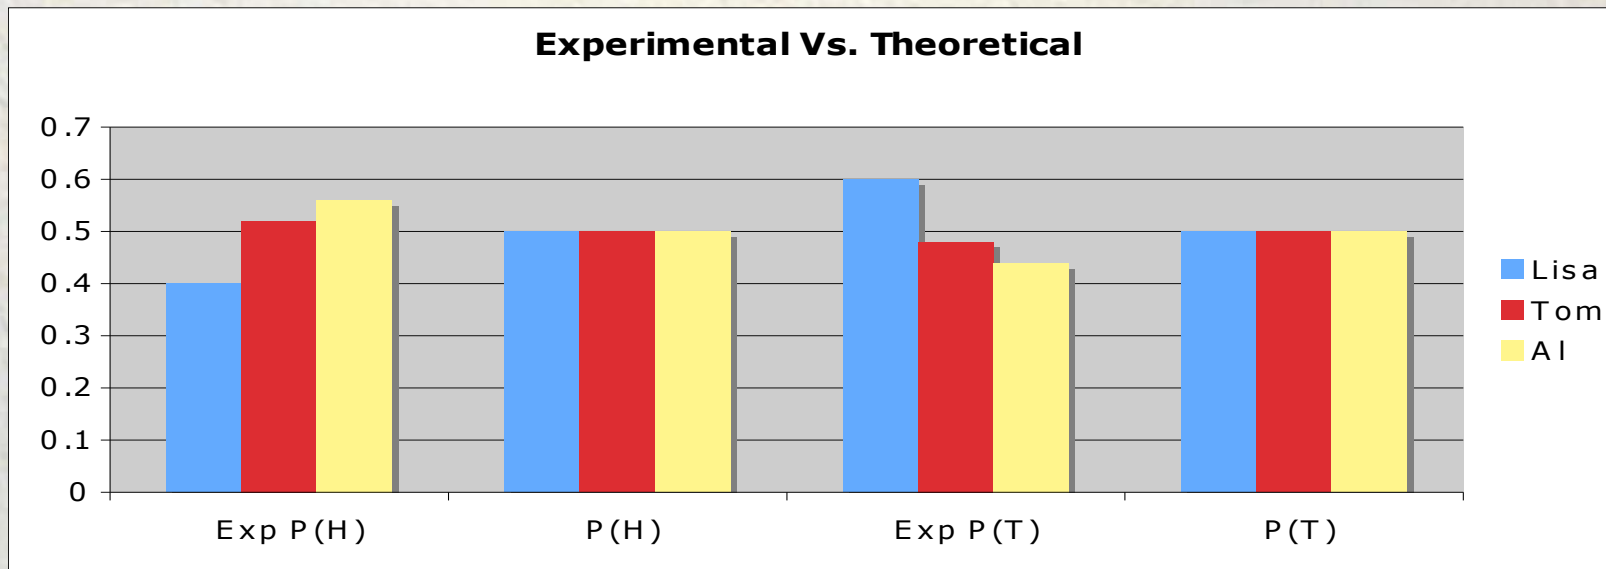

Contrast Experimental and theoretical probability

Three students tossed a coin 50 times individually.

- Lisa had a head 20 times. ($20/50 = 0.4$)
- Tom had a head 26 times. ($26/50 = 0.52$)
- Al had a head 28 times. ($28/50 = 0.56$)
- Please compare their results with the theoretical probability.
- It should be 25 heads. ($25/50 = 0.5$)

Contrast Experimental and theoretical probability

Summary of toss up results						
Name	# of Heads	Exp P(H)	P(H)	# of Tails	Exp P(T)	P(T)
Lisa	20	0.4	0.5	30	0.6	0.5
Tom	26	0.52	0.5	24	0.48	0.5
Al	28	0.56	0.5	22	0.44	0.5

Lesson Review

- Probability as a measure of likelihood
- There are two types of probability
- Theoretical--- theoretical measurement and can be found without experiment
- Experimental--- measurement of a actual experiment and can be found by recording experiment outcomes
